

## Some Results on Smarandache Semigroups

Asst.Prof. Sajda Kadhum Mohammed  
Dep.of Math. , College Of Education for Girls, Al-Kufa University

**Abstract:** We discuss in this paper a Smarandache semigroups, a Smarandache cyclic semigroups and a Smarandache Lagrange semigroups. We prove that the Smarandache semigroup  $Z_{2p}$  with multiplication modulo  $2p$  where  $p$  is an odd prime have two subgroups of order  $p-1$  and we prove that  $Z_{2p}$  is a S-cyclic semigroup and Smarandache weakly Lagrange semigroup and we prove that some results about a Smarandache inverse in groups and a Smarandache conjugate in groups.

### 1.Introduction :

Padilla Raul introduced the notion of Smarandache semigroups [1], in the year 1998 in the paper entitled Smarandache Algebraic Structures. Since groups are perfect structures under a single closed associative binary operation, it has become infeasible to define Smarandache groups. Smarandache semigroups are the analog in the Smarandache ideologies of the groups where Smarandache semigroup is defined to be the semigroup  $A$  such that a proper subset of  $A$  is a group (with respect to the same binary operation).

In this paper we prove some results in a Smarandache Lagrange semigroups [1],[2], a Smarandache cyclic semigroups [2], a Smarandache inverse in groups and a Smarandache conjugate in groups [2], we use Matlab programming to check our results in this paper.

### 2.Definitions and Notations:

**Definition 2.1:** The Smarandache semigroup (S-semigroup) is defined to be a semigroup  $A$  such that a proper subset of  $A$  is a group (with respect to the same binary operation), [2].

**Example 2.2:** Let  $z_{14} = \{0, 1, \dots, 13\}$  be the semigroup under multiplication modulo 14. Clearly the set  $A = \{1, 13\} \subset z_{14}$  is a group under multiplication modulo 14, so  $z_{14}$  is the Smarandache semigroup, [2].

**Definition 2.3:** Let  $S$  be a S-semigroup if every subset  $A$  of  $S$  which is a subgroup is cyclic then we say  $S$  is a Smarandache cyclic, [2].

**Definition 2.4:** Let  $S$  be a S-semigroup if there exist at least a proper subset  $A$  of  $S$  which is a cyclic subgroup under the same operation of  $S$  then we say  $S$  is a Smarandache weakly cyclic, [2].

**Definition 2.5:** Let  $G$  be a group. An element  $x \in G \setminus \{1\}$  is said to have a Smarandache inverse  $y$  in  $G$  if  $xy=1$  and for  $a, b \in G \setminus \{1, x, y\}$ , we have  $xa=y$  (or  $ax=y$ ),  $yb=x$  (or  $by=x$ ) with  $ab=1$ , [2].

**Definition 2.6:** Let  $G$  be a group. An element  $x \in G$ ;  $x$  is said to have a Smarandache conjugate  $y$  in  $G$  if

- 1-  $x$  is conjugate to  $y$  (that is there exist  $a \in G$  such that  $x=aya^{-1}$ ).
- 2-  $a$  is conjugate with  $x$  and  $a$  is conjugate with  $y$ , [2].

**Definition 2.7:** Let  $S$  be a finite S-semigroup. We say  $S$  is a Smarandache non-Lagrange semigroup if the order of none of the subgroups of  $S$  divides the order of the S-semigroup, [2].

**Definition 2.8:** Let  $S$  be a finite S-semigroup. If the order of every subgroups of  $S$  divides the order of the S-semigroup  $S$  then we say  $S$  is a Smarandache Lagrange semigroup, [2].

**Definition 2.9:** Let  $S$  be a finite S-semigroup. If there exist at least one subgroup  $A$  that is a proper subset ( $A \subset S$ ) having the same operation of  $S$  whose order divides the order of  $S$  then we say that  $S$  is a Smarandache weakly Lagrange semigroup, [2].

**Definition 2.10:** Let  $(G, *)$  be a finite group and  $p$  a prime. A subgroup  $(P, *)$  of  $(G, *)$  is said to be a Sylow  $p$ -subgroup if  $(P, *)$  is a  $p$ -group and is not properly contained in any other  $p$ -subgroup of  $(G, *)$  for the same prime number  $p$ , [3].

**Definition 2.11:** Two integers  $a$  and  $b$ , not both of which are zero, are said to be relatively prime whenever  $\text{g.c.d.}(a, b) = 1$ , [4], [5].

**Theorem 2.12:** The linear congruence  $ax \equiv b \pmod{n}$  have a solution if and only if  $d \mid b$ , where

$d = \text{g.c.d.}(a, n)$ . If  $d|b$ , then it have  $d$  mutually incongruent solutions modulo  $n$ , [4].

**Theorem 2.13:** Let  $a, b, n \in \mathbb{Z}$ ,  $n > 0$ . If  $\text{g.c.d.}(a, n) = 1$  then the congruence  $az \equiv b \pmod{n}$  have a unique solution  $z$ ; moreover, any integer  $z'$  is a solution iff  $z' \equiv z \pmod{n}$ , [6].

**Theorem 2.14:** If  $n$  is a positive integer then  $ax \equiv 1 \pmod{n}$  have a unique solution iff  $\text{g.c.d.}(a, n) = 1$ , [6], [7].

**Theorem (Sylow) 2.15:** Let  $(G, *)$  be a finite group of order  $p^k q$ , where  $p$  is a prime not dividing  $q$ . Then  $(G, *)$  have a Sylow  $p$ -subgroup of order  $p^k$ , [3], [7], [8].

**Theorem 2.16:** Let  $G$  be a finite group,  $H$  a  $p$ -subgroup of  $G$ , if  $H$  is normal subgroup then  $H$  contains in each Sylow  $p$ -subgroup in  $G$ , [3].

**Theorem 2.17:** let  $(G, *)$  be a group of order  $pq$  where  $p$  and  $q$  prime numbers,  $p < q$ , if  $q \not\equiv 1 \pmod{p}$  then  $(G, *)$  cyclic, [3], [9].

**Theorem 2.18:** If  $G$  is an abelian group of order  $n$  having at most one cyclic for each prime divisor  $P$  of  $n$  then  $G$  is cyclic, [10].

### 3. The Main Results

**Proposition 3.1:** let  $Z_{2p}$  be the semigroup under the multiplication modulo  $2P$ ,  $P$  is an odd prime then  $Z_{2p}$  have two subsets of order  $P-1$  where they are subgroups of it under the same operation.

**Proof:** Let  $(Z_{2p}, \cdot_{2p})$  be the semigroup under multiplication modulo  $2P$ ,  $P$  is an odd prime, the order of  $Z_{2p}$  is  $2p$ , now, to compuse a subset of  $Z_{2p}$  without zero element in it we must cancel zero element and  $P$  because that  $0 \cdot x = x \cdot 0 = 0$  and  $P \cdot x = x \cdot P = 0 \quad \forall x \in Z_{2p}$ , [4],

so we have all odd and even number in it except  $0$  and  $P$ , now, we have two subsets,  $H$  and  $K$  where  $H = \{2n : n \in \mathbb{Z} \text{ and } 0 < n \leq p-1, n \neq p\}$   
 $= \{2, 4, \dots, 2P-2\}$

and  $K = \{2n+1 : n \in \mathbb{Z} \text{ and } 0 \leq n \leq P-1, 2n+1 \neq P\}$   
 $= \{1, 3, \dots, 2p-1\}$ .

To prove that  $(H, \cdot_{2p})$  is a group,

If  $x, y \in H \subseteq Z_{2p}$  then  $xy \in Z_{2p}$ ,

since  $x, y$  even so  $xy$  is even and by use the multiplication mod  $2P$  which is even, since  $H$  contains each element of  $Z_{2p}$  which is even so  $xy \in H$ .

It is clear that  $H$  is associative under multiplication mod  $2P$ ,

now, let  $x, 1+P \in H$  where  $P$  is an odd prime so

$x \cdot (1+p) = x + xp \pmod{2p} = x$ ,  $(1+p) \cdot x = x \pmod{2p}$  since  $x$  is even,

so  $1+p$  is the identity element of  $H$ .

Now let  $x, y \in H$  then  $xy \equiv yx \equiv 1+p \pmod{2p}$  have two incongruent solution, since  $\text{g.c.d.}(y, 2p) = 2$ ,

let the first is  $x_0$  so the other is  $x_0 + \frac{2p}{2} = x_0 + p$ ,

[4], since  $p$  is an odd prime so just one of them must be even, so just one of them belong to  $H$ , therefore  $H$  contains one solution of this equation so  $H$  have an inverse for each element of it, so  $(H, \cdot_{2p})$  is a group.

Now to prove that  $(K, \cdot_{2p})$  is a group,

If  $x, y \in K \subseteq Z_{2p}$  then  $xy \in Z_{2p}$ , since  $x, y$  odd so  $xy$  is odd and by use the multiplication mod  $2P$   $xy$  still odd and since  $K$  contains each element of  $Z_{2p}$  except  $p$  which is odd so  $xy \in K$ , it is clear that  $K$  is associative under multiplication mod  $2P$  and the identity element is  $1$ ,

now, let  $x, y \in K \subseteq Z_{2p}$  then  $xy \equiv yx \equiv 1 \pmod{2p}$  have a unique solution, since  $\text{g.c.d.}(y, 2p) = 1$ , [11], so  $x$  have  $y$  as inverse so  $(K, \cdot_{2p})$  is a group, it is clear that the order of  $H = o(Z_{2p}) - \{\text{odd number}\} -$

$\{0\} = 2p - \frac{2p}{2} - 1 = p - 1$ , and

the order of  $K = o(Z_{2p}) - \{\text{even number}\} - \{p\} = 2p - \frac{2p}{2} - 1 = p - 1$ .

#### Remark:

It important to note that any other subgroup of  $Z_{2p}$  must be a subset of  $H$  or  $K$ , since if there is a subset  $M$  of  $Z_{2p}$  contains element from  $H$  and  $K$  so there are several cases:

Case 1: If  $1 \notin M$  and  $x \in K \cap M$  so  $x$  have no identity element so  $M$  is not a group.

Case 2: if  $1, 1+p \in M$  and  $x \in H \cap M$  so  $x$  have two identity element  $1$  and  $1+p$  so  $M$  is not a group.

Case 3: if  $1 \in M$  and  $1+p \notin M$  and  $x, y \in M$  such that  $x \in H$  and  $y \in K$  then since  $H$  is even so  $xy = z$  for some  $z \in H$ , then  $y = x^{-1}z$  is even number but  $y \in K$  so we have contradiction.

**Proposition 3.2:** let  $Z_{2p}$  be the semigroup under the multiplication modulo  $2P$ ,  $P$  is an odd prime then  $Z_{2p}$  is a cyclic Smarandache semigroup if  $p-1 \neq 2^\alpha$ .

**Proof:** Let  $(Z_{2p}, \cdot_{2p})$  be the semigroup under multiplication modulo  $2P$ ,  $P$  is an odd prime, and  $p-1 \neq 2^\alpha$ .

By remark above there is no subgroup of  $Z_{2p}$  not contains in the subgroup of  $H$  or  $K$ , so we must to prove that  $H$  and  $K$  cyclic then use the fact that each subgroup of cyclic subgroup is a cyclic subgroup,[3].

First we prove that  $H$  is cyclic ,

we know that each  $x \in Z$  can be written as a product of prime number , [5],[7],so

$x = p_1^{\alpha_1} p_2^{\alpha_2} \dots p_L^{\alpha_L}$  where  $p_i \ i=1, \dots, L$ , is a prime number , then

$O(H) = 2^{\alpha_1} p_2^{\alpha_2} \dots p_L^{\alpha_L}$  where  $o(H)$  is an even number , then there are two cases:

Case 1: If  $o(H) = 2^{\alpha_1} p_1^{\alpha_2}$  where  $p_1 \geq 3$ ,

Since  $p_1 \geq 3$  and  $2 \nmid p_1 \pmod{2p}$ , so  $H$  is cyclic,[8],[9].

Case 2: if  $o(H) = 2^{\alpha_1} p_2^{\alpha_2} \dots p_L^{\alpha_L}$  where each  $p_i \neq 2$ , since  $H$  is commutative so each subgroup of it must be normal subgroup ,[8], then by sylow theorem for each  $p_i$ ,  $H$  contains a unique sylow  $p_i$ -subgroup ( $T_i$ ) of order  $p_i$  for each  $i$ , since it is normal and the order of it is prime so it is cyclic.

Now we want to prove that this group is unique for each  $p_i$ , suppose that there exist cyclic subgroup of order  $p_i$ , say  $M$  since it is normal so it is contains in each Sylow  $p_i$ -subgroup in  $Z_{2p}$ , [3], since  $T_i$  is Sylow  $p_i$ -subgroup so

$M \subseteq T_i$  so  $o(M) \leq o(T_i)$

but  $o(M) = p_i$  so  $M = T_i$ , therefore this group is unique for each  $p_i$ , so for every  $p_i$  divisor of order  $H$  there exist a unique cyclic subgroup have order  $p_i$  so  $H$  is a cyclic subgroup, [3],[8],

by use the similar way we can prove that  $K$  is a cyclic subgroup ,

so  $Z_{2p}$  is a Smarandache cyclic semigroup.

**Example:** let  $(z_{14}, \cdot_{14})$  be the semigroup under the multiplication modulo 14, since  $14 = 2p$  where  $p=7$  so by above proposition there are two subsets of it of order  $p-1=6$ ,  $H = \{2, 4, 6, 8, 10, 12\}$  and  $K = \{1, 3, 5, 9, 11, 13\}$ , the tables of them are given by

$\cdot_{14}$	1	3	5	9	11	13
1	1	3	5	9	11	13
3	3	9	1	13	5	11
5	5	1	11	3	13	9
9	9	13	3	11	1	5
11	11	5	13	1	9	3
13	13	11	9	5	3	1

$\cdot_{14}$	2	4	6	8	10	12
2	4	8	12	2	6	10
4	8	2	10	4	12	6
6	12	10	8	6	4	2
8	2	4	6	8	10	12
10	6	12	4	10	2	8
12	10	6	2	12	8	4

Note that  $H$  is a cyclic subgroup generated by 10 and 12, i.e.  $H = \langle 10 \rangle = \langle 12 \rangle$ , and  $1+p=8$  is the identity and  $K$  is a cyclic subgroup generated by  $K = \langle 3 \rangle = \langle 5 \rangle$ .

**Proposition 3.2:** let  $Z_{2p}$  be the semigroup under the multiplication modulo  $2p$ ,  $p$  is an odd prime then  $Z_{2p}$  is a Smarandache weakly lagrange semigroup if  $p-1 \neq 2^\alpha$ .

**Proof:**  $(Z_{2p}, \cdot_{2p})$  be the semigroup under multiplication modulo  $2p$ ,  $p$  is an odd prime and  $p-1 \neq 2^\alpha$ , by the proposition above there exist two subgroups of  $Z_{2p}$ ,  $H$  and  $K$  with order  $p-1$ ,  $o(Z_{2p}) = 2p$ ,  $H$  and  $K$  with order  $= p-1 \neq 2^\alpha$ , since  $2p$  did not divisible by  $p-1$  so  $Z_{2p}$  did not a Smarandache lagrange semigroup but it is weakly Lagrange semigroup since  $o(H)$  is even and for each prime  $q$  divisor of  $o(H)$  there exist a subgroup of order  $q$  and since 2 divided  $o(H)$  so there exist a subgroup  $M$  of  $H$  of order 2, since  $M \subset H \subset Z_{2p}$  so  $M \subset Z_{2p}$  and  $\frac{o(Z_{2p})}{o(M)} = \frac{2p}{2} = p$ , so  $Z_{2p}$  is Smarandache weakly lagrange semigroup.

**Proposition 3.3:** Let  $(G, *)$  be a group and  $x \in G$ , if  $x$  have Smarandache inverse, then in general need not have Smarandache conjugate.

**Proof:** we prove this by an example. Let  $G = \langle a \rangle = \langle 1 \ 2 \ 3 \ 4 \rangle$  be a group with usual composition of mappings, such that  $(1 \ 2 \ 3 \ 4) \in S(4)$  which is the semigroup of all mappings from  $x = \{1, 2, 3, 4\}$  to  $x = \{1, 2, 3, 4\}$  under the usual composition of mappings. It is clear that  $a^4 = I$  where  $I = (1)$  and the order of  $G = 4$ , note that  $aa^3 = I$  and  $a^2 \in G \setminus \{1, a, a^3\}$  such that  $a^2 a = a^3$  and  $a^3 a^2 = a$ , so  $a$  have a Smarandache inverse but there is no  $x \in G$  such that  $x$  conjugate to  $a$  so  $a$  have not Smarandache conjugate

**Proposition 3.4:** Let  $(G, *)$  be a group and  $x \in G$ , if  $x$  have Smarandache conjugate, then in general need not have Smarandache inverse.

**Proof:** we prove this by an example. Let

$$S_3 = \{I = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, p_1 = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, p_2 = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix}, \\ p_3 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}, p_4 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}, p_5 = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix}\}$$

be the symmetric group of the degree 3. Now we have  $p_1$  conjugate with  $p_2$  since

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix},$$

so  $p_1$  conjugate with  $p_2$  by  $p_3$ .

And since

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}, p_3 \text{ conjugate}$$

with  $p_1$  by  $p_5$ , and

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}, p_3 \text{ conjugate}$$

with  $p_2$  by  $p_1$ , so  $p_1$  Smarandache conjugate with  $p_2$ , but  $p_1$  did not have Smarandache inverse, where  $p_1 p_1 = I$  but there is no  $x, y \in S_3 \setminus \{I, p_1\}$  such that  $x p_1 = p_1$  and  $y p_1 = p_1$  where  $xy = I$ .
